Network Request Automation Using ServiceNow Flow Designer

1. Description

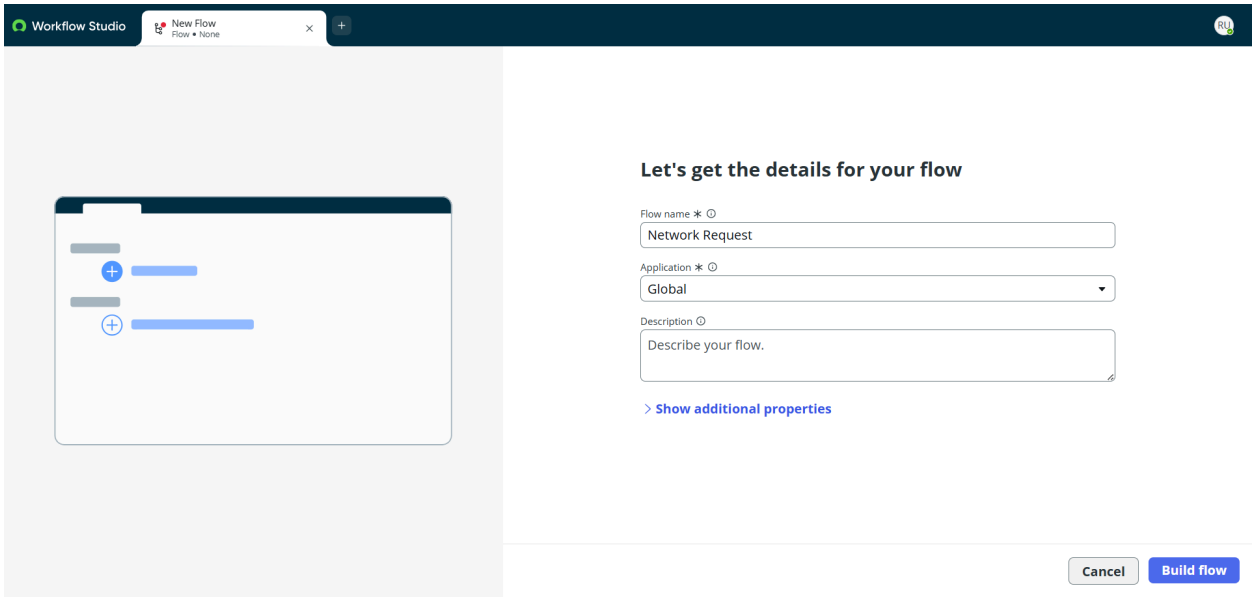
This project implements an automated workflow using ServiceNow Flow Designer to manage the complete lifecycle of Network Service Requests. The automation is triggered when a user submits a Service Catalog request and performs actions such as capturing user inputs, creating database records, sending automated notifications, routing approvals, and updating request status dynamically.

The objective of this automation is to reduce manual effort, improve efficiency, ensure consistency, and enhance tracking visibility throughout the network request process.

2. Flow Configuration

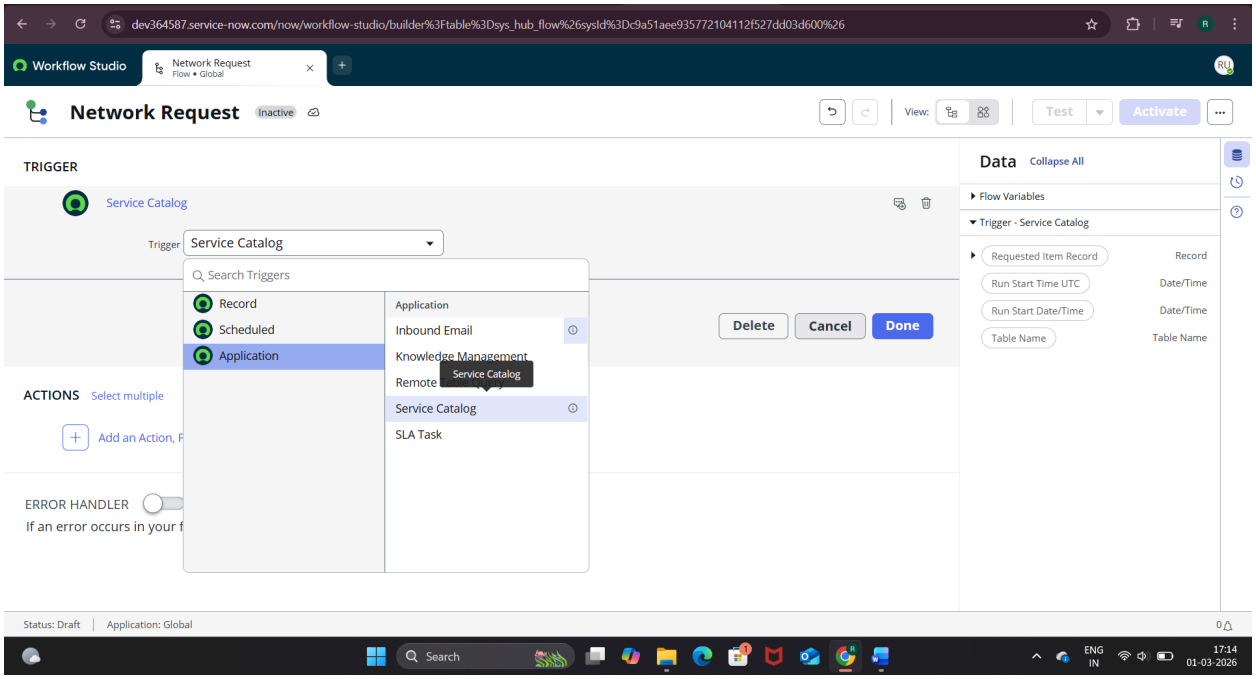
2.1 Flow Creation

A flow named “Network Request” is created in ServiceNow Flow Designer with a clear description defining its purpose. This flow acts as the central automation engine for processing all network service requests.



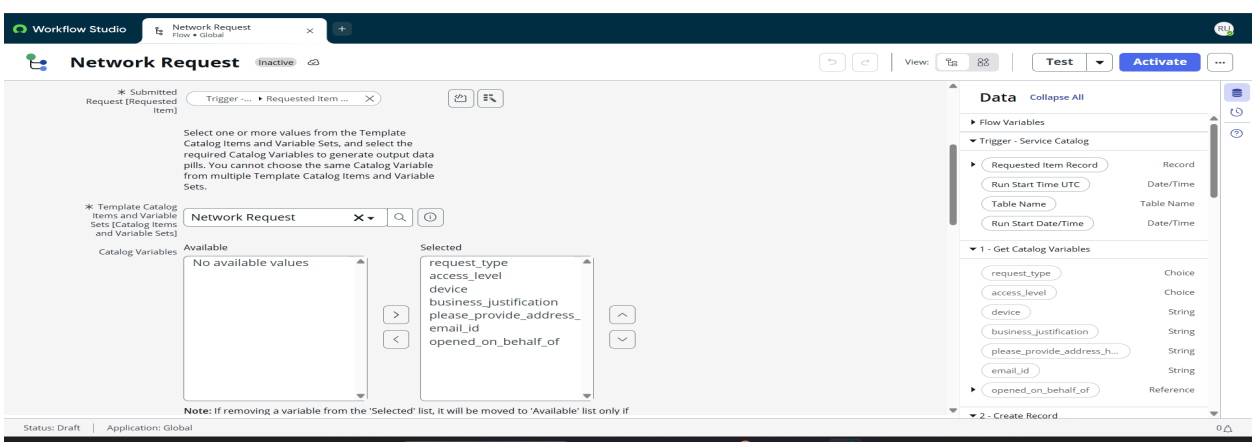
2.2 Trigger Configuration

The trigger is configured as Service Catalog, ensuring that the flow is automatically initiated whenever a user submits the Network Request catalog item. This enables real-time automation and eliminates the need for manual process initiation.



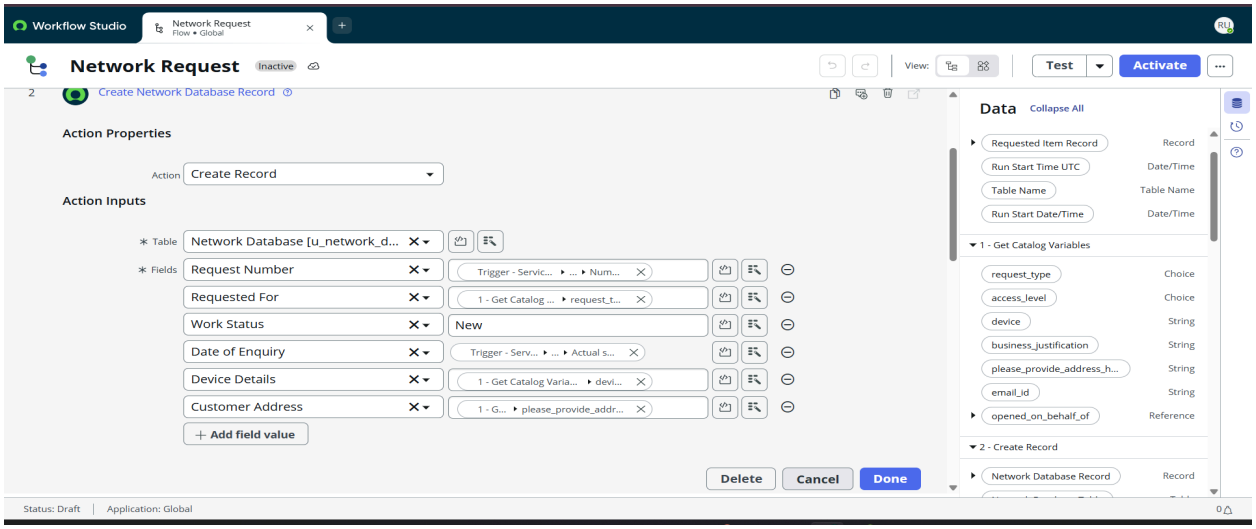
2.3 Get Catalog Variables

This step captures all the user inputs entered in the catalog form, including request type, access level, device information, business justification, email ID, and requester details. These values are stored as variables and used in subsequent workflow actions.



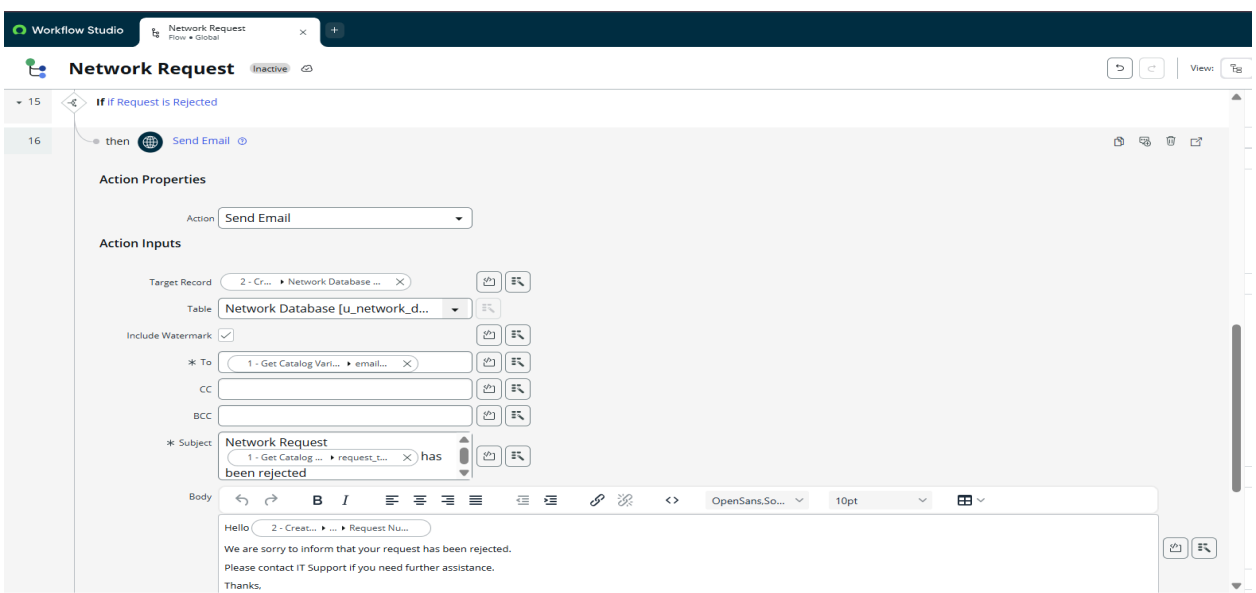
2.4 Create Network Database Record

A new record is automatically created in the **Network Database** table using the captured catalog variables. This ensures structured storage, easy tracking, and centralized management of all network requests.



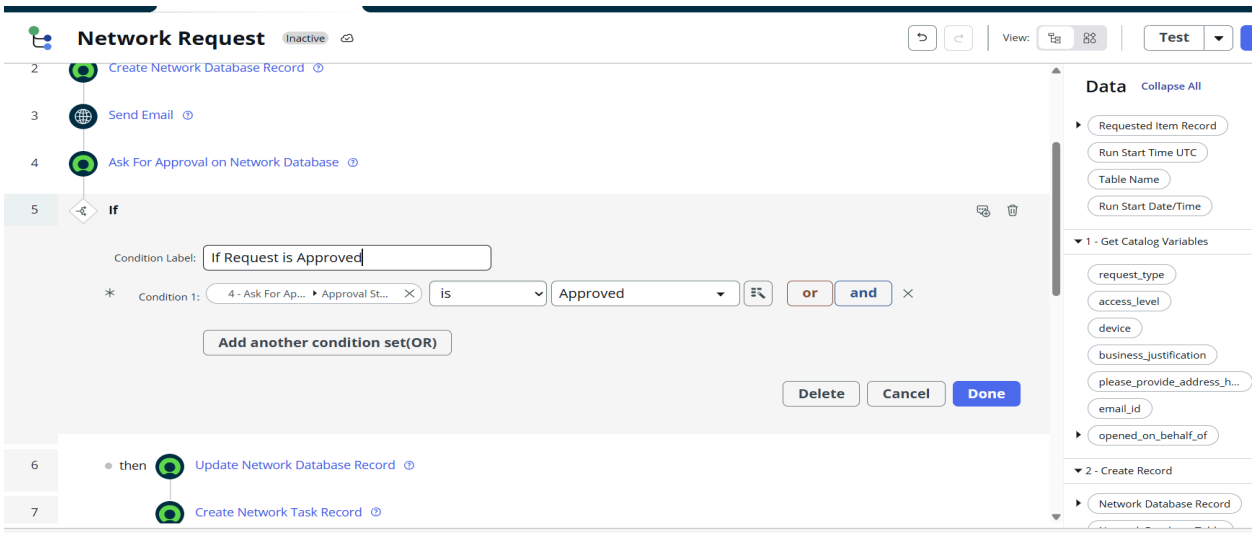
2.5 Send Email Notification

Automated email notifications are sent to the requester and stakeholders confirming request submission and providing request details. This improves communication, transparency, and user experience.



2.6 Ask for Approval

An approval workflow is configured to route the request to the appropriate authority (manager or network administrator). Approvers can either **approve or reject** the request based on business and security requirements, ensuring governance and controlled access management.

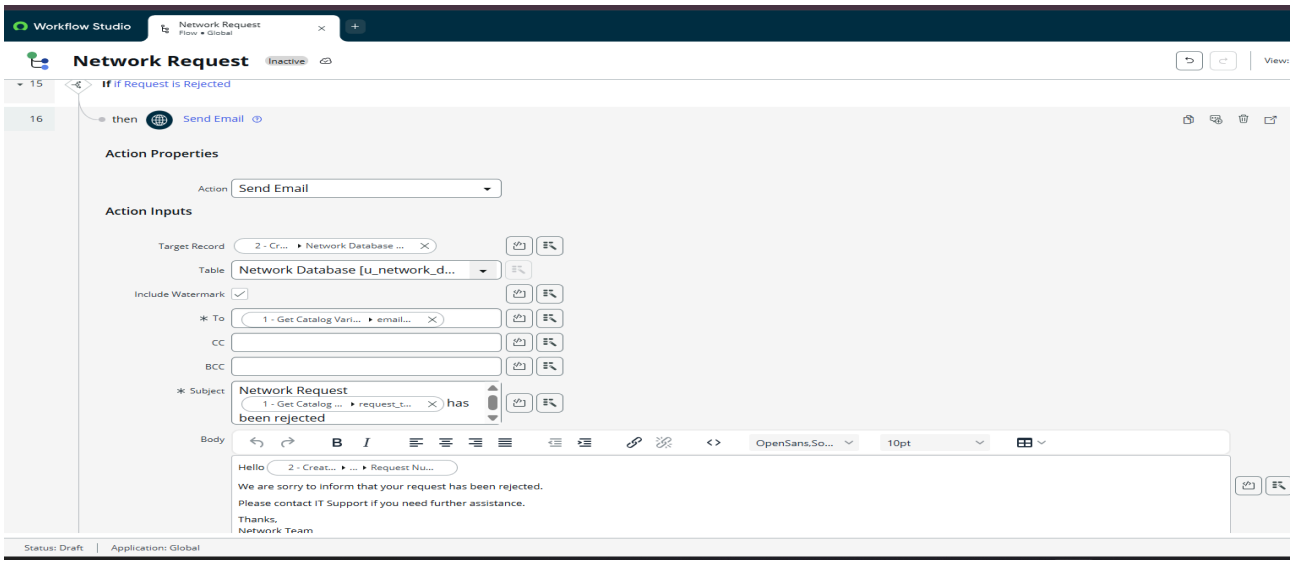


2.7 Conditional Flow Logic

Conditional logic is implemented to control the workflow based on approval outcome:

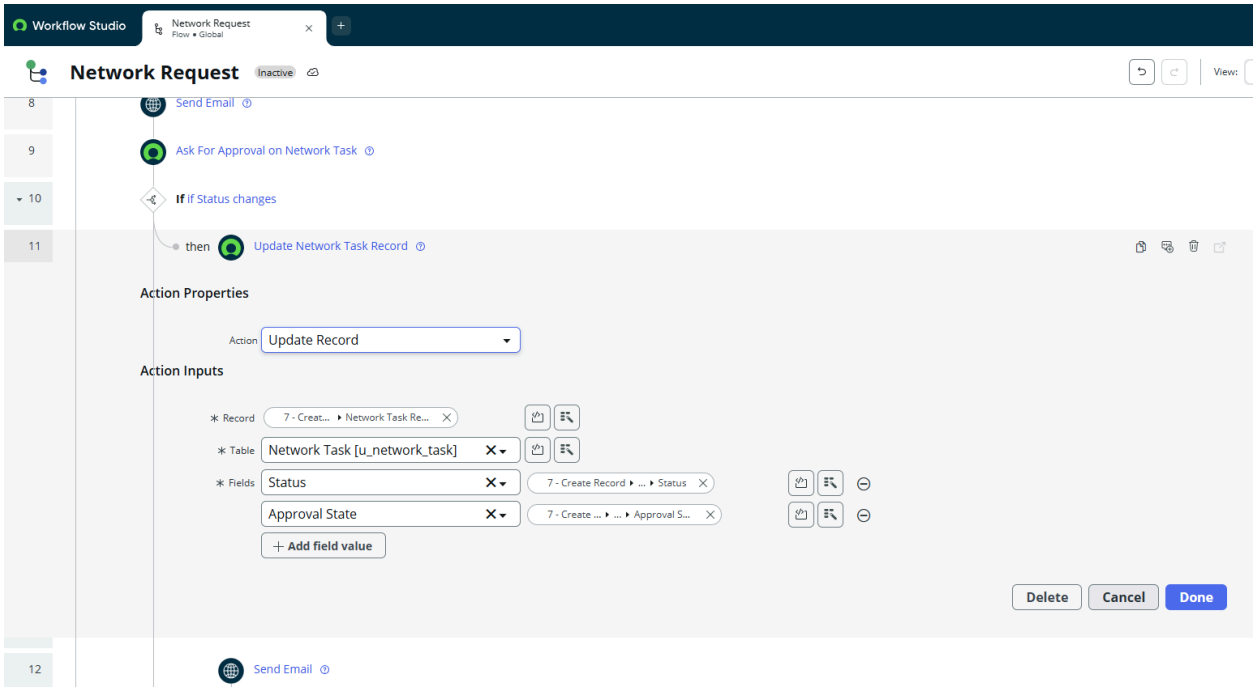
- If Approved, the flow continues with task creation, status updates, and notifications.
- If Rejected, the system sends a rejection notification and terminates the flow.

This ensures dynamic and intelligent decision-based routing.



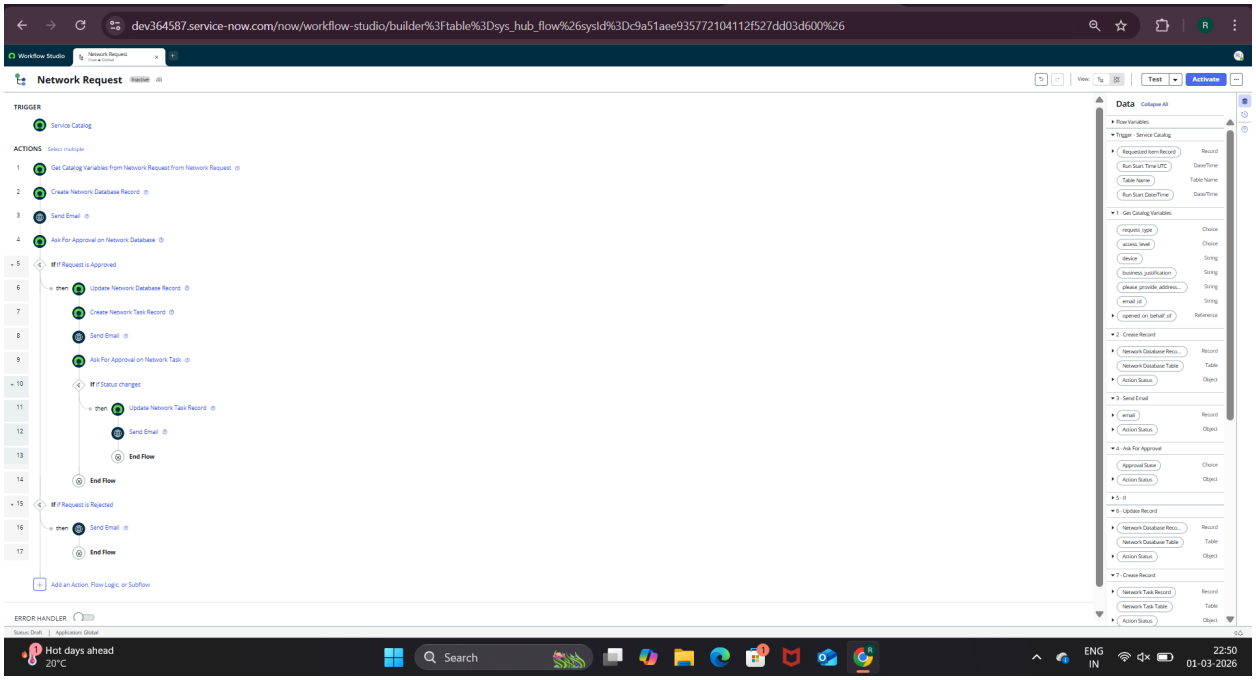
2.8 Update Records and Task Creation

After approval, the system automatically updates the status of the request and creates a Network Task record for execution. Final notifications are sent to ensure proper closure and traceability.



3. Overall Flow Summary

1. User submits the Network Request Service Catalog item.
2. The flow is automatically triggered.
3. Catalog variables are captured.
4. A record is created in the Network Database table.
5. Email notification is sent.
6. Approval is requested from the concerned authority.
7. Based on approval decision:
    - Approved → Task creation → Status update → Final notification → Flow ends
    - Rejected → Rejection notification → Flow ends



4. Benefits of Automation

- Reduces manual workload and processing delays
- Ensures standardized request handling
- Improves tracking and monitoring capabilities
- Enhances approval workflow efficiency
- Provides automated notifications and updates
- Increases process accuracy and reliability

5. Conclusion

The Network Request Automation Flow effectively streamlines the network service request process by automating record creation, approvals, task handling, and notifications. This implementation demonstrates the practical application of ServiceNow Flow Designer in building scalable, reliable, and efficient enterprise workflows.
